

Shopaholics Web App

Shopaholics web app is a Fashion e-commerce style website. With this website, we want to be able to update our users of the latest fashion trends as well as link articles from top fashion bloggers. Users will be able to create profiles that save their interests, order history, and current items in the cart if they decide not to proceed with a transaction right away. The website itself will have a variety of brands from which users can select the category they are looking for and can also search for specific products.

The API

As a team we decided to create a Fashion based website focusing on both Men's, Women's, and Children's apparel. In order to do this efficiently and with an abundance of online vendors/brands available we integrated SHOP.com API services.

Documentation: <https://developers.shop.com/externalapis/apn-services/>

The Javascript

With the use of SHOP.com API we were able to create a script that relays the specific brand in products using the JSON the API service provided. Our plan for the future of this Javascript code is to integrate it dynamically into the website, having a dropdown menu displayed in both the Men's, Women's, and Children's tab listing all the proper fashion categories and products, as well as having a functioning search for a desired product. Using Heroku would be another big step in the development process, it would allow us to keep the api_key safe and later establish a login page/cart purchase page for clients using the website.

How the Javascript Works

Current State of Shopaholics Web App

Website Home Page

Html and CSS of the website home page has the layout in place.

The website title, categories, search field in the header are complete.

The website is going to have a slider which is in progress.

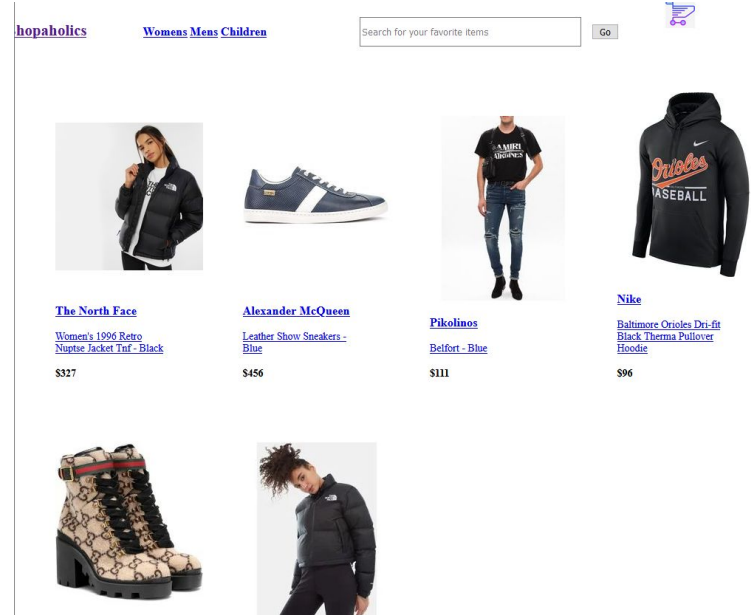

Current State of Shopaholics Web App

Website Home Page

The products section displays product images, title along with short description and pricing.

The home page currently has sections to display article from rss feed from fashion blog website.

What works

- The home page html work and loads the image slider
- The products html loads and aligns properly
- The article sections on home page displays with appropriate styles
- API is registered and we're able to use javascripts to fetch the products JSON

What does not work

- Styles for the search box and search button need to be improved
- Slider images appear with different size and we need to adjust css.
- API data for products is available in JSON but we need to incorporate that in the javascript objects and display in page HTML
- We need to pull articles from fashion RSS Feed and incorporate it in the website HTML
- We're going to work on the shopping cart and account pages
- Using Heroku would be another big step in the development process to store API keys and dynamic configurations

Pending Additions: Database

- We plan on adding a database that saves the login information.
- This will link the user profiles to their orders and also saves their shopping history.
- Their previous orders and search results
- We are currently looking into using Heroku as our cloud platform to implement this database.
